Idiotproofing

*Idiotproofing* means ensuring that a user’s input is valid.
Idiotproofing Quotes

“Idiotproofing is difficult because idiots are so clever.”

“You can't make anything idiot proof because idiots are so ingenious.”
— Ron Burns

“Idiotproofing causes evolutionary selection of more ingenious idiots.”

“Programming today is a race between software engineers striving to build bigger and better idiot-proof programs, and the Universe trying to produce bigger and better idiots. So far, the Universe is winning.” — Rich Cook

“It doesn’t really matter what effort you put into idiot-proofing a product or procedure. They will always build a better idiot.”

“Idiot-proofing assumes a finite number of idiots.”

“Campaigns to bearproof all garbage containers in wild areas have been difficult because, as one biologist put it, ‘There is a considerable overlap between the intelligence levels of the smartest bears and the dumbest tourists’.”

An Idiotproof Website

http://www.idiotproofwebsite.com/
#include <stdio.h>
#include <stdlib.h>

int main ()
{
    const int minimum_volume = 0;
    const int program_success_code = 0;
    const int program_failure_code = -1;
    float volume_in_cubic_inches;
Idiotproofing Example #2

printf("What is the volume in cubic inches?\n");
scanf("%d", &volume_in_cubic_inches);
if (volume_in_cubic_inches < minimum_volume) {
    printf("ERROR: you can’t have a negative volume in cubic inches!\n");
    printf(" volume in cubic inches!\n");
    exit(program_failure_code); /* <--- NOTICE! */
} /* if (volume_in_cubic_inches < ...) */
Idiotproofing Example #3

/*
 * ASSERT: By the time the program gets to here,
 * the volume in cubic inches must be valid.
 */
printf("The volume in cubic inches is valid.\n");
return program_success_code;
} /* main */
Idiotproofing Example #4

```
% gcc -o conversions_idiot conversions_idiot.c
% conversions_idiot
What is the volume in cubic inches? -100
ERROR: you can't have a negative volume in cubic inches!
% conversions_idiot
What is the volume in cubic inches? 100
The volume in cubic inches is valid.
```
Why We Idiotproof

- Idiotproofing ensures that input data are valid, which means that, if our program is otherwise correct, then the output will be valid as well.
- Idiotproofing allows us to assert certain properties of the data. For example, in the conversions program, properly idiotproofed input data allow us to assert that, in the calculation section, the volume in cubic inches is valid. So, our calculations can assume this fact, which sometimes can be more convenient.
The `exit` Statement #1

```c
#include <stdio.h>
#include <stdlib.h>

int main ()
{
    const int program_failure_code = -1;
    printf("This statement will be always be executed.\n");
    exit(program_failure_code);
    printf("This statement will be never be executed.\n");
}
```

% cat exitexample.c
% include <stdio.h>
% include <stdlib.h>

The `exit` statement terminates execution of a given run of a program.
The *exit* Statement #2

```
% cat exitexample.c
#include <stdio.h>
#include <stdlib.h>

int main ()
{ /* main */
    const int program_failure_code = -1;
    printf("This statement will be always be executed.\n");
    exit(program_failure_code);
    printf("This statement will be never be executed.\n");
} /* main */

% gcc -o exitexample exitexample.c
% exitexample
This statement will be always be executed.

The program terminates in a controlled, graceful way – that is, it doesn’t actually crash – without executing the remaining executable statements.
```
The `exit` Statement #3

```c
#include <stdio.h>
#include <stdlib.h>

int main ()
{
    const int program_failure_code = -1;
    printf("This statement will be always be executed.\n");
    exit(program_failure_code);
    printf("This statement will be never be executed.\n");
}
```

Notice that the `exit` statement takes an `int` argument. This argument represents the value that will be returned by the program to the operating system (for example, Linux).

By convention, returning 0 from a program to the OS means that the program completed successfully, so if the program is exiting prematurely, then you should return a non-zero value.
The `exit` Statement #4

```c
#include <stdio.h>
#include <stdlib.h>

int main ()
{
    const int program_failure_code = -1;
    printf("This statement will be always be executed.\n");
    exit(program_failure_code);
    printf("This statement will be never be executed.\n");
}

% gcc -o exitexample exitexample.c
% exitexample
This statement will be always be executed.
```

**Jargon**: In the context of running a program, all of the following terms are generally used to mean the same thing: exit, stop, halt, terminate, abort.
printf("This statement will be always be executed.\n");
exit(program_failure_code);
printf("This statement will be never be executed.\n");

Notice that the symbol for an exit is also an oval.
A New File to `#include`

```c
% cat exitexample.c
#include <stdio.h>
#include <stdlib.h>

int main ()
{
    const int program_failure_code = -1;
    printf("This statement will be always be executed.\n");
    exit(program_failure_code);
    printf("This statement will be never be executed.\n");
}

% gcc -o exitexample exitexample.c
% exitexample
This statement will be always be executed.
```

To use an `exit` statement, you **MUST** include an additional header file, **IMMEDIATELY AFTER** `stdio.h`:

`#include <stdlib.h>`
exit Statement Inside an if Block #1

```c
if (volume_in_cubic_inches <
    minimum_volume) {
    printf("ERROR: you can't have a negative");
    printf(" volume in cubic inches!\n");
    exit(program_failure_code); /* <--- NOTICE! */
} /* if (volume_in_cubic_inches < ...) */
```

When you put an `exit` statement inside an `if` block, the `exit` statement will be executed only in the event that the appropriate clause of the `if` block is entered, and then only after all prior statements in that clause of the `if` block have already been executed.
exit Statement Inside an if Block #2

```c
if (volume_in_cubic_inches <
    minimum_volume) {
    printf("ERROR: you can’t have a negative");
    printf(" volume in cubic inches!\n");
    exit(program_failure_code); /* <--- NOTICE! */
} /* if (volume_in_cubic_inches < ...) */
```

In the above example, the `exit` statement is executed only in the event that the volume in cubic inches is negative, and only after executing the `printf` statement that precedes it.
exit Statement Inside an if Block #3

if (volume_in_cubic_inches < minimum_volume) {
    printf("ERROR: you can’t have a negative");
    printf(" volume in cubic inches!\n");
    exit(program_failure_code); /* <--- NOTICE! */
} /* if (volume_in_cubic_inches < ...) */

Notice that the exit statement DOESN’T have to have a comment after it.
**exit Statement Inside an if Block #4**

```c
if (volume_in_cubic_inches < minimum_volume) {
    printf("ERROR: you can't have a negative");
    printf(" volume in cubic inches!\n");
    exit(program_failure_code); /* <--- NOTICE! */
} /* if (volume_in_cubic_inches < ...) */
```

Notice that the `exit` statement is inside the `if` block and therefore is indented **MORE** than the `if` statement.
Idiotproofing Example’s Flowchart

```c
if (volume_in_cubic_inches < minimum_volume) {
    printf("ERROR: you can’t have a negative");
    printf(" volume in cubic inches!
");
    exit(program_failure_code);
} /* if (volume_in_cubic_inches < ...) */
```
