23. String Comparison Example #3
Character String Declaration

In C, we declare a **character string** like so:

```c
char my_name[my_name_length+1];
```

Notice that a character string is declared **exactly like** a `char` array; in fact, it **is** a `char` array. The only difference in the declaration is that the length of the array of `char` elements that represents the string is **one greater** than the length of the string.
Character String Terminator

The last character in any C character string is the 
**null character**, called **NUL**, which corresponds to 
integer value 0:

' \0 '

Thus, the **null character** (integer 0) is often referred to as the 
**character string terminator**.

In general, a numeric value that is used to indicate that a 
particular state has been reached – for example, the end of a 
list – is called a **sentinel** value.

So, the character string terminator **NUL** is a sentinel that 
indicates the end of the string in question.
How String Printing Really Works #1

% cat charstrassn.c
#include <stdio.h>
#include <string.h>

int main ()
{
    /* main */
    const int my_name_length = 12;
    const int program_success_code = 0;
    char my_name[my_name_length + 1];
    strcpy(my_name, "Henry Neeman");
    printf("My name is %s.\n", my_name);
    return program_success_code;
}
/* main */

% gcc -o charstrassn charstrassn.c
% charstrassn
My name is Henry Neeman.

The program on the next page behaves **identically** to this program.
How String Printing Really Works #2

% cat printstring.c
#include <stdio.h>
#include <string.h>
int main()
{
    /* main */
    const int my_name_length = 12;
    const int program_success_code = 0;
    char my_name[my_name_length + 1];
    int index;
    strcpy(my_name, "Henry Neeman");
    printf("My name is ");
    index = 0;
    while (my_name[index] != \0) {
        printf("%c", my_name[index]);
        index++;
    } /* while (my_name[index] != \0) */
    printf(".
");
    return program_success_code;
} /* main */
% gcc -o printstring printstring.c
% printstring
My name is Henry Neeman.
String Copy Function: `strcpy`

The C standard library function `strcpy` copies a character string into a `char` array.

```c
strcpy(my_name, "Henry Neeman");
```

Notice that you **CANNOT SIMPLY ASSIGN ONE STRING TO ANOTHER:**

```c
/* THIS WON'T WORK! */
my name = "Henry Neeman"; /* NO! */
```

```c
#include <stdio.h>
#include <string.h>

int main ()
{
    /* main */
    const int my_name_length = 12;
    const int program_success_code = 0;
    char my_name[my_name_length + 1];
    char my_name2[my_name_length + 1];
    strcpy(my_name, "Henry Neeman");
    printf("My name is %s.\n", my_name);
    strcpy(my_name2, my_name);
    printf("My name is %s.\n", my_name2);
    return program_success_code;
}
/* main */
```

% gcc -o charstrcpy charstrcpy.c
% charstrcpy
My name is Henry Neeman.
My name is Henry Neeman.
String Placeholder

In a `printf` statement, the placeholder for a character string is:

```
%s
```
String Placeholder Example

```c
#include <stdio.h>
#include <string.h>

int main ()
{
    const int my_name_length = 12;
    const int program_success_code = 0;
    char my_name[my_name_length + 1];
    char my_name2[my_name_length + 1];
    strcpy(my_name, "Henry Neeman");
    printf("My name is %s.\n", my_name);
    strcpy(my_name2, my_name);
    printf("My name is %s.\n", my_name2);
    return program_success_code;
}
```

```bash
% cat charstrcpy.c
% gcc -o charstrcpy charstrcpy.c
% charstrcpy
My name is Henry Neeman.
My name is Henry Neeman.
```
The **strlen** Function

The C Standard Library function **strlen** returns the length of the string that is passed to it, **EXCLUDING THE STRING TERMINATOR:**

```
my_name_length = strlen(my_name);
```
strlen Function Example

```c
#include <stdio.h>
#include <string.h>

int main ()
{
    printf("strlen(\042Henry Neeman\042) = %d\n",
        '\042', '\042', strlen("Henry Neeman"));
    return 0;
}
```

```bash
% cat charstrlen.c
#include <stdio.h>
#include <string.h>

int main ()
{
    /* main */
    printf("strlen(%cHenry Neeman%c) = %d\n",
        '\042', '\042', strlen("Henry Neeman"));
    return 0;
}
/* main */

% gcc -o charstrlen charstrlen.c
% charstrlen
strlen("Henry Neeman") = 12
```
Dynamic Allocation of Strings

You can dynamically allocate the space for a string, just as you can for any other array:

```c
my_name = (char*)malloc(sizeof(char) * (my_name_length + 1));
```
String Dynamic Allocation Example #1

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int main () {
    /* main */
    const int program_success_code = 0;
    const int program_failure_code = -1;
    char* my_name = (char*)NULL;
    int my_name_length;
```
my_name_length = strlen("Henry Neeman");
my_name =
  (char*)malloc(sizeof(char) *
               (my_name_length + 1));
if (my_name == (char*)NULL) {
  printf("ERROR: can’t allocate ");
  printf("char array my_name.\n");
  exit(program_failure_code);
} /* if (my_name == (char*)NULL) */
strcpy(my_name, "Henry Neeman");
printf("My name is %s.\n", my_name);
free(my_name);
my_name = (char*)NULL;
return program_success_code;
} /* main */
gcc -o charstrdyn charstrdyn.c
charstrdyn
My name is Henry Neeman.
Passing a String as a Function Argument

Passing a string to a function as an argument is just like passing any other kind of array argument, whether statically allocated or dynamically allocated, except that you DON’T also need to pass a length argument (since its length is implied by its string terminator):

```c
int main ()
{
    char my_name[my_name_length + 1];
    char* my_name2 = (char*)NULL;
...
    print_a_string(my_name);
    ...
    print_a_string(my_name2);
    ...
} /* main */

void print_a_string (char* the_string)
```
String Function Argument Example #1

#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int main ()
{
    const int my_name_length = 12;
    const int program_success_code = 0;
    const int program_failure_code = -1;
    char my_name[my_name_length + 1];
    char* my_name2 = (char*)NULL;
    void print_a_string(char* the_string);
}
String Function Argument Example #1

```c
strcpy(my_name, "Henry Neeman");
printf("My name is %s.\n", my_name);
print_a_string(my_name);
my_name2 =
  (char*)malloc(sizeof(char) * 
    (strlen(my_name) + 1));
if (my_name2 == (char*)NULL) {
  printf("ERROR: can’t allocate ");
  printf("char array my_name2.\n");
  exit(program_failure_code);
} /* if (my_name2 == (char*)NULL) */
strcpy(my_name2, my_name);
printf("My name is still %s.\n", my_name);
print_a_string(my_name2);
free(my_name2);
my_name2 = (char*)NULL;
return program_success_code;
} /* main */
```
void print_a_string (char* the_string)
{ /* print_a_string */
    const int program_failure_code = -1;
    printf("The string that was passed is:\n");
    if (the_string == (char*)NULL) {
        printf("ERROR: can’t print a ");
        printf("non-existent string\n");
        printf(" in print_a_string.\n");
        exit(program_failure_code);
    } /* if (the_string == (char*)NULL) */
    printf("%s\n", the_string);
} /* print_a_string */

% gcc -o charstrpass charstrpass.c
% charstrpass
My name is Henry Neeman.
The string that was passed is:
Henry Neeman
My name is still Henry Neeman.
The string that was passed is:
Henry Neeman
String Comparisons

Just as numeric values can be compared, so can string values. However, strings aren’t scalars.
In C, two strings are defined to be equal if they have the exact same contents.
In C, strings are compared using the `strcmp` function from the C Standard Library.

The relational operators CANNOT CANNOT CANNOT CANNOT CANNOT CANNOT CANNOT be used to compare strings!
String Comparison is Case Sensitive

String comparison is **case sensitive**.

Thus, if two strings are identical, except that, in a single character, they differ by case – for example, an "H" for one string corresponds to an "h" for the other – then they WON’T be equal.

For example:

"Henry" is not equal to "henry"
String Comparison Example #1

```c
#include <stdio.h>
#include <string.h>

int main ()
{
    /* main */
    const int my_name_length = 12;
    const int program_success_code = 0;
    char my_name[my_name_length + 1];
    char my_name2[my_name_length + 1];
    char my_first_name[my_name_length + 1];
    char my_first_name_lower[my_name_length + 1];
    char my_last_name[my_name_length + 1];
```
String Comparison Example #2

```c
strcpy(my_name, "Henry Neeman");
strcpy(my_name2, my_name);
strcpy(my_first_name, "Henry");
strcpy(my_first_name_lower, "henry");
strcpy(my_last_name, "Neeman");
printf("strcmp(%s,%s) = %2d\n",
        my_name, my_name2,
        strcmp(my_name, my_name2));
printf("strcmp(%s,%s) = %2d\n",
        my_first_name, my_first_name_lower,
        strcmp(my_first_name, my_first_name_lower));
printf("strcmp(%s,%s) = %2d\n",
        my_last_name, my_first_name,
        strcmp(my_last_name, my_first_name));
return program_success_code;
```
String Comparison Example #3

% gcc -o charstrcmp charstrcmp.c
% charstrcmp
strcmp(Henry Neeman, Henry Neeman) = 0
strcmp(Henry, henry) = -1
strcmp(Neeman, Henry) = 1

Notice that the return value for `strcmp` can be interpreted as:

- **zero**: the strings are equal  
- **negative**: the first string is less  
- **positive**: the first string is greater
